(54) Title: SYSTEM AND METHOD FOR PROVIDING LOCATION INFORMATION OF A MOBILE STATION IN A COMMUNICATION SYSTEM

(57) Abstract

A system (101) interconnects with a communication system via standard interfaces to provide location information related to a mobile station (103) within the communication system. The system (101) includes location device equipment (121) which generates raw location information of the mobile station (103) based on input received from a message compatible with the communication system. The system (101) also includes a mediation device (118) which stores location information related to the mobile station (103) and also interfaces with radio control functionality within the communication system. The system (101) further includes a location calculator (124) which determines the location information related to the mobile station (103) based on the raw location information of the mobile station (103) and which also provides the location information related to the mobile station (103) to the mediation device (118) for storage and to an intelligent network device (106) for use in location based services (127).

**SYSTEM AND METHOD FOR PROVIDING
LOCATION INFORMATION OF A
MOBILE STATION IN A COMMUNICATION SYSTEM**

5

FIELD OF THE INVENTION

The present invention relates, in general, to communication
10 systems and, more particularly, to providing location information of
mobile stations in such communication systems.

15

BACKGROUND OF THE INVENTION

The primary problem associated with location-based services is
the lack of an open and interoperable architecture for the collection,
storage, and presentation of location data on a per mobile station basis.
The problem can be decomposed into five specific problem areas. The
20 first problem area is the service problem, where there exists no standard
means for the service logic to trigger the network to collect call-related
RF data and location determination equipment (LDE) to collect
location-related RF data. The second problem area is the radio problem,
where there exists no defined standard which allows a base station
25 subsystem (BSS) and an LDE to share call-related RF data. The third
problem area is the network problem, where there exists no defined
standard which allows all types of data (call-related RF data, location-
related RF data, service-related data, etc.) associated with location
services to be transported and presented to different network elements
30 which need to access them. The fourth problem area is the
synchronization problem, which manifests itself due to the dynamic
nature of the mobile communication system (call handoff and
termination are examples of dynamic events). The synchronization
problems prevent the service logic from correlating data and events for
35 a specific mobile station within the communication system, which

itself may result in a false location determination of the mobile station. Finally, the fifth problem area is the mobility management problem, where there exists no standard means for the trigger, collection, and transfer of call-related data as the mobile station being located is
5 handed-over between network elements.

Thus, a need exists for a method and system to provide location information of a mobile station which overcomes the above deficiencies.

10

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 generally depicts a preferred embodiment system architecture including network entities and functional entities which
15 provide location information of a mobile station in accordance with the invention.

FIG. 2 generally depicts an exemplary call flow diagram which provides location information of a mobile station in accordance with the invention.

20 FIG. 3 generally depicts an alternate embodiment system architecture where the LDF functionality is provided in the BSS of FIG. 1 to provide location information of a mobile station in accordance with the invention.

25

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

A system interconnects with a communication system via standard interfaces to provide location information related to a mobile
30 station within the communication system. The system includes location device equipment which generates raw location information of the mobile station based on input received from a message compatible with the communication system. The system also includes a mediation device which stores location information related to the
35 mobile station and also interfaces with radio control functionality

within the communication system. The system further includes a location calculator which determines the location information related to the mobile station based on the raw location information of the mobile station and which also provides the location information 5 related to the mobile station to the mediation device for storage and to an intelligent network device for use in location based services.

The mediation device is coupled to a base station system which provides the radio control functionality for communicating to the mobile station. The mediation device is further coupled to third party 10 services which utilize the location information related to the mobile station stored therein. The location information related to the mobile station and stored in the mediation device is updated based on the requirements of the third party services. Channel and call related information is provided to the location device equipment via a 15 message compatible with the communication system. In the preferred embodiment, the communication system is a GSM digital communication system and the message is a CALL TRACE message which gathers channel and call related information. The CALL TRACE message to gather channel and call related information is triggered via 20 a CALL TRACE REQUEST message originated from the intelligent network.

Generally stated, a method of providing location information related to a mobile station in a communication system to third party services includes the steps of analyzing a request for location based 25 services related to the mobile station and requesting a location of the mobile station based on those services supported by the mobile station. The method further includes the steps of invoking, via a request message, the gathering of raw location information of the mobile station using channel and call related information associated with the 30 mobile station and determining final location information related to the mobile station utilizing the raw location information of the mobile station to provide the final location information to the third party services. The analyzing further comprises the step of analyzing a service key and CAMEL subscriber information (CSI) associated with 35 the mobile station. The channel and call information used to gather

raw location information of the mobile station is provided to location determination functionality via a CALL TRACE message. The method applies equally to mobile stations which are compatible with a GSM digital communication system, a GSM-based GPRS digital communication system, a CDMA digital communication system or a personal communication system.

FIG. 1 generally depicts a preferred embodiment system architecture 100 including network entities and functional entities which provide location information of a mobile station 103 in accordance with the invention. In the preferred embodiment, the system architecture 100 is based on the Global System for Mobile Communication (GSM) digital communication system, as is well known in the art. The network entities, and their related intercoupling and functionality, are described below. Also for clarity, a list of abbreviations for the network entities and their related functionality are provided below.

20	MS	Mobile Station
	SCP	Service Control Point
	gsmSCF	GSM Service Control Function
	HLR	Home Location Register
	MSC/VLR	Mobile Switching Center/Visitor Location Register
	SSF	Service Switching Function
	BSS	Base Station Subsystem
25	RCF	Radio Control Function
	MD	Mediation Device
	MF	Mediation Function
	LIB	Location Information Base
	LDE	Location Determination Equipment
30	LDF	Location Determination Function
	LC	Location Calculator
	LCF	Location Control Function
	CAMEL	Customized Application for Mobile Enhanced Logic
35	CSI	CAMEL Subscriber Information

Referring to FIG. 1, a service control point (SCP) 106 is coupled to a home location register (HLR) 109 via a GSM-based "MAP" interface as is well known in the art. In the preferred embodiment, the SCP 106 is based on the Customized Application for Mobile Enhanced Logic

(CAMEL) intelligent network model as defined in "GSM Recommendation 02.78 titled Digital Cellular Telecommunications System (Phase 2+); Customized Applications for Mobile network Enhanced Logic (CAMEL); Service definition (Stage 1)", "GSM 5 Recommendation 03.78 titled Digital Cellular Telecommunications System (Phase 2+); Customized Applications for Mobile network Enhanced Logic (CAMEL)" and "GSM Recommendation 09.78 titled Digital Cellular Telecommunications System (Phase 2+); CAMEL Application Part (CAP) Specifications" the disclosure of which are 10 herein incorporated by reference. The SCP 106 provides a GSM service control function (gsmSCF) as is defined in the above cited GSM Recommendation 03.78.

As is also well known in the art, both SCP 106 and HLR 109 are coupled to the Mobile Switching Center (MSC)/Visitor Location 15 Register (VLR) 112 via the CAMEL-based "CAP" interface and the GSM-based "MAP-D" interface respectively. The MSC/HLR 112 provides a service switching function (SSF) and is itself coupled to a base station subsystem (BSS) 115 via the GSM-based "A" interface. While not shown in FIG. 1, it is well known to those skilled in the art that BSS 115 20 is primarily responsible for providing services for communicating to MS 103, such services including, *inter alia*, communication set-up, channel assignment and radio frequency (RF) transmission and reception. Such functions are generally referred to as radio control 25 functions (RCFs). To provide such RCF functionality, BSS 115 is comprised of a base station controller (BSC) and a base transceiver station (BTS), both of which are well known and thus not shown for clarity. The SCP 106, HLR 109, MSC/VLR 112 and BSS 115 generally comprise a typical GSM digital communication system as is well known in the art.

30 FIG. 1 also includes a mediation device (MD) 118, location determination equipment (LDE) 121 and a location calculator (LC) 124 which provide location information related to MS 103 in accordance with the invention. As shown in FIG. 1, the MD 118 is coupled to the BSS 115 via International Telecommunication Union (ITU) standard 35 "X.25". The MD 118 further includes a mediation function (MF), and

the X.25 interface is used to transfer data from the RCF of the BSS 115 to the MF of the MD 118. The MD also includes a location information base (LIB) which is essentially a management information base (MIB), as defined by ITU's Telecommunications Management Network (TMN)

5 Recommendations M.3100, M.3200 and M.3400. As described with reference to FIG. 1, the LIB functionality is used as a location information focal point for the storage and retrieval of location data in accordance with the invention.

Also coupled to the MD 118 is location determination equipment (LDE) 121 and location calculator (LC) 124. The LDE 121 is a hardware and/or software element which includes a location determination function (LDF). The LDF is a functional entity which interfaces with the LIB and collects raw location information related to the MS 103 which is eventually stored in the LIB. The LC 124 includes a location calculation function (LCF) which calculates the final location of MS 103 based on the raw location information captured by the LDE and stores the final location information of the MS 103 in the LIB. The LCF also interfaces with the gsmSCF of the SCP 109 which allows the gsmSCF to obtain location information for a specific mobile station, for example 10 MS 103 in accordance with the invention. As can be seen in FIG. 1, the LC 124 is coupled to the SCP 109 via the "X" interface. This is a TCAP-based interface which is used by the LCF to report final location information from the LCF to the gsmSCF, but may likewise be used by the gsmSCF to query the LCF to obtain location information related to 15 20 25 MS 103 in accordance with the invention.

The functional entity LDF within LDE 121 and the functional entity LCF within LC 124 are coupled to the functional entity MF within the MD 118 via an ITU-based "CMIP/CMISE" interface. For the LDF-to-MF coupling, the CMIP/CMISE interface is used by the LDF to retrieve 30 call-related RF data from the LIB via the MF and store raw location information in the LIB via the MF. For the LCF-to-MF coupling, the CMIP/CMISE interface is used by the LCF to retrieve raw location-related data from the LIB via the MF and store final location data in the LIB via the MF.

The MF within the MD 118 is a functional entity which allows access to LIB. As shown in FIG. 1, the entities RCF, LCF, LDF, and gsmSCF access the LIB via the MF. Essentially, the MF acts as a converter between the RCF and other functional entities such as the 5 LDF and the LCF and provides access to the LIB through the CMIP/CMISE interface. The MF implements a point code addressing scheme which is used by the RCF to identify where data is to be routed.

In the preferred embodiment, the LDF within the LDE 121 collects and reports raw location information of a RF channel which is 10 assigned to communicate to a specific mobile station, for example MS 103. In the preferred embodiment, the LDE 121 and its corresponding LDF are shown separate from the BSS 115 and the MS 103, but one skilled in the art will appreciate that it could equally be embedded in the MS 103, in the BSS 115, or be distributed across each of the MS 103 15 and the BSS 115. Multiple LDFs may be used to locate MS 103.

The LCF within the LC 124 obtains raw location information of the particular RF channel from the LIB and performs algorithmic calculations on the information to compute the final location of the MS 103 associated with the particular RF channel. The LCF then stores this 20 final location information in the LIB. As stated above, multiple LDFs may cooperate to collect location information for a single MS. In this scenario, the LCF correlates all data feeds from all LDFs to a specific MS. The LCF is responsible for delivering the current location information related to the MS 103 based on the identity of the MS 103. In the 25 preferred embodiment, the identity of the MS 103 is provided via an international mobile station identification (IMSI) parameter or a temporary mobile station identification (TMSI) parameter. The IMSI and TMSI parameters are described in GSM Recommendation 04.08.

The LIB is the data focal point for all location services supported 30 by the system architecture 100 in accordance with the invention. The structure of the LIB is based on ITU's telecommunication management network (TMN) specifications which allows for modeling of the MS 103 as a managed object (MO). Each MO is described in the LIB in terms of its attributes, behavior, operations, notifications, etc. One key attribute 35 of MS 103 as a MO is the location of MS 103. The LIB uses Management

Applications that provide controlled access to the location information data. For example, a third party service 127 (which is a location based service) has the privilege to query the LIB to find out how many mobile stations are available in a certain area without knowing the identity of
5 these mobiles. This access is accomplished via the ITU-based "CMIP/CMISE" interface.

For the LDE 121 to collect raw RF data for the specific MS 103, the LDE 121 needs to know the exact channel and call information associated with the specific MS 103. So that the system in accordance
10 with the invention is compatible with the GSM digital communication system, the "CALL TRACE" facility as described in "GSM 12.08 78 Digital cellular telecommunications system (Phase 2+); Subscriber and Equipment Trace" is used to collect and report call-related RF data to the LDE 121. The MSC/VLR 112 initiates the CALL TRACE after data is
15 stored in the LIB and thus the LDE 121 has access thereto.

In one scenario where location information related to MS 103 is obtained, the gsmSCF identifies a call to MS 103 as requiring a location service via the "SERVICE KEY" which is part of the CAMEL Subscriber Information (CSI). The concept of the service key and the CSI is
20 described in the above-mentioned GSM Recommendation 02.78, but generally, the service key identifies the location based service to be invoked. The gsmSCF requests location information of the specific MS 103 either during call setup (origination or termination) or after the call is connected. After identifying the call as requiring location services,
25 the gsmSCF instructs the MSC/VLR 112 to initiate a CALL TRACE. Upon receiving instructions from the gsmSCF to initiate the CALL TRACE, the SSF within the MSC/VLR 112 triggers the RCF within the BSS 115 to begin a call trace for a given call.

From the MS and BSS perspective, the call setup procedure for a
30 CAMEL subscriber (i.e., MS 103) is no different than the call setup procedure for any other subscriber. When MS 103 is identified to be a CAMEL subscriber, the MSC/VLR 112 initiates the first contact with the gsmSCF and passes to it the CSI of MS 103 which contains the SERVICE KEY. If the SERVICE KEY indicates that the service is a location service,
35 the gsmSCF instructs the MSC/VLR 112 to initiate a CALL TRACE at

the BSS 115 to collect location data. To initiate this CALL TRACE, a new message "TRACE CALL REQUEST" is introduced which identifies the destination of the network element which will receive the CALL TRACE data as well as the type of data to be collected.

5 For location services, the CALL TRACE data which is relevant includes mobile station identity (IMSI, TMSI), radio channel information, timing advance and power control information, base-station identity code of the cell in which the call is established and measurement report data. The MSC/VLR 112 uses the CALL TRACE
10 data type received from the gsmSCF to instruct the BSS 115 to collect only the required call related data so as not to impact the signaling performance of the BSS 115 and its associated link "A" interface link to the MSC/VLR 112. Stated differently, only the minimum amount of data is requested to keep the amount of signaling to a minimum.

15 The MSC can also invoke a CALL TRACE at the BSS 115 for a call in which a Signaling Connection Control Part (SCCP) connection has already been established. At the invocation of CALL TRACE, the BSS 115 starts collecting CALL TRACE data and forwards the data to the MD 118 which in turn triggers the location data collection at the LDE 121
20 and location determination at the LC 124. The LC 124 establishes a call relationship with the gsmSCF for the call in which location information related to MS 103 is desired. Location data collected at the LDE 121 is forwarded to the LC 124 via the LIB within the MD 118. Using the location data, the LC 124 computes the location information
25 and passes this information to the gsmSCF.

As shown in FIG. 1, third party services 127 are easily connected to the MD 118 in accordance with the invention. In prior art systems, the location information was buried in the MSC/VLR 112 and not available to third parties who can beneficially employ the location information. By coupling MD 118, LDE 121 and LC 124 to the known prior art communication system, the location information is easily accessed by any third party service 127 which can leverage the use of the location information. As such, depending on the service which requires location information, the determination of location may be a
30 either a continuous event for the life time of a call or can be terminated
35

if continuous location determination is not needed for the call. In the latter scenario, the LC 124 decides to cease data gathering via CALL TRACE at the BSS 115 either via the MD 118 or the MSC/VLR 112. As such, data gathering for location determination (and thus location 5 determination itself) in accordance with the invention is dependent upon the requirements of third party services 127 requesting such location information.

FIG. 2 generally depicts an exemplary call flow diagram which provides location information of a mobile station in accordance with 10 the invention. For clarity, the description of FIG. 2 is provided in terms of the functionality of each of the network elements shown in FIG. 1. For a mobile originated or terminated call, the SSF initiates the first contact with the gsmSCF and passes the CSI of the MS 103 to it. The gsmSCF analyzes 203 the SERVICE KEY of the CSI and if the SERVICE 15 KEY indicates a location service, the gsmSCF instructs 206 the SSF to trigger the BSS 115 to trace the call via the TRACE CALL REQUEST message.

Upon receiving the TRACE CALL REQUEST message from the gsmSCF, the SSF triggers the RCF of BSS 115 to invoke a CALL TRACE 20 as described in the above-mentioned "GSM 12.08 78 Digital cellular telecommunications system (Phase 2+); Subscriber and Equipment Trace." At this point, the CALL TRACE must include the IMSI and TMSI of MS 103. The SSF passes the address of the MD to the RCF as part of the TRACE CALL REQUEST message. A relationship between 25 the BSS 115 and the MD 118 is established 212 which indicates the start of a CALL TRACE. The MF of the MD 118 notifies/triggers 215 the LDF of LDE 121 and notifies/triggers 218 the LCF of LC 124 of an incoming call which requires location determination. Within the triggering identified at step 215, channel and call related information associated 30 with the particular MS 103 is provided to the LDE 121 via the CALL TRACE message. A relationship between the LCF and the gsmSCF is then established 221 and the RCF then sends 224 the CALL TRACE data to the LIB of the MD 118 via the MF for storage in the LIB.

Next, LDF of the LDE 121 retrieves the call-related RF data from 35 the LIB and then collects 227 raw location data. The raw location data

collected is then stored in the LIB. The raw location data is retrieved
230 by the LCF from the LIB where the final location information is
computed 233. The final location information is then sent 236 to the
gsmSCF and is also stored in the LIB for use by third party services 127
5 as required. Once the gsmSCF receives the final location information,
the gsmSCF continues 239 the handling of the call as a normal CAMEL
call. The final location information is also sent 242 to the LIB within
the MD for storage, where it can be accessed and beneficially utilized in
accordance with the invention by third party services 127 coupled to the
10 MD.

Location information access for a call in progress is provided to
the gsmSCF during call setup as described in with reference to FIG. 2.
Location information is updated and stored in the LIB after the call is
connected for the duration of the call. If the gsmSCF requires location
15 updates after the call is connected, it must query the LDF of the LC 124.
As such, the LC 124 supports synchronous location update (i.e., a
request and response) as well as asynchronous location update (i.e.,
timer-based or event-based updates). The gsmSCF uses the IMSI or
TMSI of the mobile station to identify the MS 103 to be located.

20 In an alternate embodiment, the LDF can be implemented as part
of the RCF within the BSS 115. FIG. 3 generally depicts this alternate
embodiment system architecture 300 where the LDF functionality is
provided in the BSS of FIG. 1 to provide location information of a
mobile station in accordance with the invention. For the sake of clarity,
25 the LDF and the RCF are shown as having separate functionality within
the BSS 115. However, the operation and call flow as described with
reference to FIG. 2 is exactly the same; the only difference between the
architecture of FIG. 1 and FIG. 3 is the location of the LDF. In this
embodiment, the apparatus in accordance with the invention can
30 logically be thought of as the configuration of the MD 118 and the LC as
shown by the line 303.

The technique of providing location information related to a
mobile station is not limited by the type of mobile station employed.
For example, the mobile station could be a mobile station compatible
35 with a code division multiple access (CDMA) digital communication

system as defined in TIA/EIA/IS-95-A, "Mobile Station-Base Station Compatibility Standard for Dual Mode Wideband Spread Spectrum Cellular System," March 1995 or could likewise be a mobile station compatible with ANSI J-STD-008, "Personal Station-Base Station 5 Compatibility Requirements for 1.8 to 2.0 GHz Code Division Multiple Access (CDMA) Personal Communication Systems," August 1995. Additionally, while the preferred embodiment has been described in relation to a GSM digital communication system, different versions of such a system continue to evolve. One proposal currently being 10 considered for a GSM-based system currently evolving is defined in the European Telecommunications Standards Institute (ETSI) draft document TS 03 64, V2.1.1 titled "Digital Cellular Telecommunications System (Phase 2+); General Packet Radio Service (GPRS); Overall Description of the GPRS Radio Interface; Stage 2 (GSM 03.64, version 15 2.1.1)." The architecture proposed in accordance with the invention is compatible to provide location information related to any one of these types of mobile stations in accordance with the invention.

While the invention has been particularly shown and described with reference to a particular embodiment, it will be understood by 20 those skilled in the art that various changes in form and details may be made therein without departing from the spirit and scope of the invention. The corresponding structures, materials, acts and equivalents of all means or step plus function elements in the claims below are intended to include any structure, material, or acts for 25 performing the functions in combination with other claimed elements as specifically claimed.

What I claim is:

Claims

1. A system for providing location information related to a mobile station in a communication system, the system comprising:
 - 5 location device equipment for generating raw location information of the mobile station;
 - 10 a mediation device, coupled to the location device equipment, for storing location information related to the mobile station and for interfacing with radio control functionality;
 - 15 a location calculator, coupled to the mediation device and an intelligent network device, for determining final location information related to the mobile station based on the raw location information of the mobile station and for providing the final location information related to the mobile station to the mediation device for storage and to the intelligent network device for use in location based services.
2. The system of claim 1, wherein the mediation device is further coupled to a base station system which provides the radio control functionality for communicating to the mobile station and to third party services which utilize the final location information related to the mobile station stored therein.
- 25 3. The system of claim 2, wherein the final location information related to the mobile station and stored in the mediation device is updated based on the requirements of the third party services.
- 30 4. The system of claim 1, wherein channel and call related information is provided to the location device equipment via a message compatible with the communication system, wherein the message is a CALL TRACE message, triggered via a CALL TRACE REQUEST message originated from the intelligent network, which gathers channel and call related information when the communication system is a GSM digital communication system.

5. A system for providing location information related to a mobile station in a communication system to third party services, the system comprising:
 - 5 a mediation device, having as an input raw location information of the mobile station, for storing final location information related to the mobile station and for interfacing with radio control functionality;
 - 10 a location calculator, coupled to the mediation device and an intelligent network device, for determining the location information related to the mobile station based on the raw location information of the mobile station and for providing the location information related to the mobile station to the mediation device for storage and to the intelligent network device for use in location based services.
- 15 6. The system of claim 5, wherein the raw location information of the mobile station is generated by location device equipment having location determination functionality, wherein the location device equipment having location determination functionality is located either internal or external to a base station subsystem.
- 20 7. The system of claim 5, wherein the final location information related to the mobile station and stored in the mediation device is updated based on the requirements of the third party services.

8. A method of providing location information related to a mobile station in a communication system to third party services, the method comprising the steps of:
 - 5 analyzing a request for location based services related to the mobile station and requesting a location of the mobile station based on those services supported by the mobile station;
 - 10 invoking, via a request message, the gathering of raw location information of the mobile station using channel and call related information associated with the mobile station; and
 - 15 determining final location information related to the mobile station utilizing the raw location information of the mobile station and providing the final location information to the third party services.
- 15 9. The method of claim 8, wherein the step of analyzing further comprises the step of analyzing a service key and CAMEL subscriber information (CSI) associated with the mobile station.
- 20 10. The method of claim 8, wherein the mobile station is compatible with either a GSM digital communication system, a GSM-based GPRS digital communication system, a CDMA digital communication system or a personal communication system.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US98/09714

A. CLASSIFICATION OF SUBJECT MATTER

IPC(6) :H04Q 7/34, 7/20, 7/08; G01S 5/02; H04M 11/00
US CL :455/432, 433, 435, 436, 456, 457, 422

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 455/432, 433, 435, 436, 456, 457, 422

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	US 5,568,153 A (BEILIVEAU) 22 OCTOBER 1996, SEE ABSTRACT AND FIGURES 1-4	1-10
Y	US 5,537,610 A (MAUGER ET AL) 16 JULY 1996, SEE ABSTRACT AND FIGURES 1-27	1-10
Y	US 5,396,543 A (BEESON, JR. ET AL) 7 MARCH 1995, SEE ABSTRACT AND FIGURES 1-25	1-10

Further documents are listed in the continuation of Box C.

See patent family annex.

•	Special categories of cited documents:	T	later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
A	document defining the general state of the art which is not considered to be of particular relevance		
E	earlier document published on or after the international filing date	X*	document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
L	document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	Y*	document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
O	document referring to an oral disclosure, use, exhibition or other means	&	document member of the same patent family
P	document published prior to the international filing date but later than the priority date claimed		

Date of the actual completion of the international search

14 AUGUST 1998

Date of mailing of the international search report

25 SEP 1998
